Considering problem 2 that the sensors data from 24 hours is requied to be processed, the size of matrix constructed for differential calculation is extremely large (4311×4311). It requires approximately 25GB of GPU memory if the data is stored in 64-bit floting point form which exceed the limit of household PC. Although we rent a A800 GPU to obtain the accurate results, this is not pratical in because of high cost.
